**(54) TISSUS A BASE DE STRUCTURE TRESSEE DESTINES AUX  
COURROIES POUR PRESSES A PATINS**

**(54) BRAIDED BASE FABRICS FOR SHOE PRESS BELTS**

(57) L'invention concerne une courroie sans fin imprégnée de résine, destinée à une presse ou à une calandre à ligne de contact allongée du type à sabot; ladite courroie comprend un tissu de support ayant la forme d'une structure tréssée multicouche; chaque couche constitutive de ladite structure est connectée aux couches adjacentes par au moins un fil enchevêtré, ceci pour empêcher la séparation des couches. Le tissu de support représente une bande sans fin dont au moins la surface interne est enduite d'une substance à base de résine polymère telle que la polyuréthane. La substance à base de résine polymère imprègne la structure du tissu de support et le rend ainsi étanche à l'eau et à l'huile.

(57) A resin-impregnated endless belt for a long nip press or calender of the shoe type has a base fabric in the form of a multilayer braided structure wherein each of the constituent layers are connected to those adjacent thereto by at least one interlocking yarn to inhibit interlayer delamination. The base fabric is in the form of an endless loop, at least the inner surface of which is coated with a polymeric resin material, such as polyurethane. The polymeric resin material impregnates the structure of the base fabric, rendering it impermeable to oil and water.

Braided Base Fabrics for Shoe Press BeltsBackground of the Invention1. Field of the Invention

The present invention relates to mechanisms for extracting water from a web of material, and more particularly from a fibrous web being processed into a paper product on a papermaking machine. Specifically, the present invention is an impermeable belt designed for use on a long nip press on a papermaking machine. The belt may also be used in other papermaking and paper-processing applications, such as calendering.

2. Description of the Prior Art

During the papermaking process, a fibrous web is formed on a forming wire by depositing a fibrous slurry thereon. A large amount of water is drained from the slurry during this process, after which the newly formed web proceeds to a press section. The press section includes a series of press nips, in which the fibrous web is subjected to compressive forces designed to remove water therefrom. The web finally proceeds to a drying section which includes heated dryer drums around which the web is directed. The heated dryer drums reduce the water content of the web to a desirable level through evaporation.

Rising energy costs have made it increasingly desirable to remove as much water as possible from the web prior to its entering the dryer section. The dryer drums are often heated from within by steam and related costs can be substantial especially when a large amount of water needs to be removed from the web.

Traditionally, press sections have included a series of nips formed by pairs of adjacent cylindrical press rolls. In recent years, the use of long press nips has been found to be advantageous over the use of 5 nips formed by pairs of adjacent press rolls. The longer the time a web can be subjected to pressure in the nip, the more water can be removed there, and, consequently, the less water will remain behind in the web for removal through evaporation in the dryer 10 section.

The present invention relates to long nip presses of the shoe type. In this variety of long nip press, the nip is formed between a cylindrical press roll and an arcuate pressure shoe. The latter has a 15 cylindrically concave surface having a radius of curvature close to that of the cylindrical press roll. When the roll and shoe are brought into close physical proximity to one another, a nip is formed which can be five to ten times longer in the machine direction than 20 one formed between two press rolls. This increases the so-called dwell time of the fibrous web in the long nip while maintaining the same level of pressure per square inch in pressing force used in a two-roll press. The result of this new long nip technology has 25 been a dramatic increase in dewatering of the fibrous web in the long nip when compared to conventional nips on paper machines.

A long nip press of the shoe type requires a special belt, such as that shown in U.S. Patent No. 30 5,238,537. This belt is designed to protect the press fabric supporting, carrying and dewatering the fibrous web from the accelerated wear that would result from direct, sliding contact over the stationary pressure shoe. Such a belt must be provided with a smooth, 35 impervious surface that rides, or slides, over the

stationary shoe on a lubricating film of oil. The belt moves through the nip at roughly the same speed as the press fabric, thereby subjecting the press fabric to minimal amounts of rubbing against the 5 surface of the belt.

Belts of the variety shown in U.S. Patent No. 5,238,537 are made by impregnating a woven base fabric, which takes the form of an endless loop, with a synthetic polymeric resin. Preferably, the resin 10 forms a coating of some predetermined thickness at least on the inner surface of the belt, so that the yarns from which the base fabric is woven may be protected from direct contact with the arcuate pressure shoe component of the long nip press. It is 15 specifically this coating which must have a smooth, impervious surface to slide readily over the lubricated shoe and to prevent any of the lubricating oil from penetrating the structure of the belt to contaminate the press fabric, or fabrics, and fibrous 20 web.

The base fabric of the belt shown in U.S. Patent No. 5,238,537 may be woven from monofilament yarns in a single- or multi-layer weave, and is woven so as to be sufficiently open to allow the impregnating 25 material to totally impregnate the weave. This eliminates the possibility of any voids forming in the final belt. Such voids may allow the lubrication used between the belt and shoe to pass through the belt and contaminate the press fabric or fabrics and fibrous 30 web.

When the impregnating material is cured to a solid condition, it is primarily bound to the base fabric by a mechanical interlock, wherein the cured impregnating material surrounds the yarns of the base 35 fabric. In addition, there may be some chemical

bonding or adhesion between the cured impregnating material and the material of the yarns of the base fabric.

While the belts shown in U.S. Patent No. 5,238,537 have proved to be durable, reliable and long-lived on long nip presses, improvements both in the structure of such belts and in methods for their manufacture are continually being made. Some of the improvements are driven by the need to prevent the 10 polymeric resin coating from delaminating from the base fabric and relate to means for improving the mechanical, and possibly chemical, interlock between the base fabric and the coating. Other improvements relate to the structure of the base fabrics 15 themselves, and are designed to make the base fabrics stronger, more durable, or to the exact dimensional specifications required for a given application. Still other improvements relate to the coating processes themselves, and have as their object the 20 complete impregnation of the base fabric and the provision of a uniformly thick coating of polymeric resin material on the inner surface of its endless configuration without the step of inverting (turning inside out) the belt during the manufacturing process.

The present invention relates to the base fabric of a long nip press belt. More specifically, the present invention is a long nip press belt having a base fabric in the form of an endless braided structure. In addition to being useful as a long nip 25 press belt, the present invention may also be used in other papermaking and paper-processing applications, such as calendering.

Summary of the Invention

Accordingly, the present invention is a resin-impregnated endless belt for a long nip press. The belt may also be used on a calender of the shoe type, 5 as both a long nip press and a calender of that type comprise a cylindrical press roll and an arcuate pressure shoe which together define a nip therebetween. The resin-impregnated endless belt passes through the nip in direct sliding contact with 10 the arcuate pressure shoe, and separates a fibrous web being treated there, and perhaps a press fabric or fabrics supporting the fibrous web, from the arcuate pressure shoe, thereby protecting the fibrous web, and the press fabric or fabrics, from damage by direct 15 sliding contact with the arcuate pressure shoe and from contamination by any lubricant on the arcuate pressure shoe.

The resin-impregnated endless belt comprises a base fabric in the form of a braided structure having 20 a plurality of braided layers of yarns. In each of the layers at least one yarn thereof extends into a contiguous layer to form an interlock therebetween. The layers are therefore interlocked with one another, and are unable to delaminate from one another. The 25 base fabric is in the form of an endless loop having an inner surface, an outer surface, a longitudinal direction and a transverse direction, and is assembled according to the teachings of commonly assigned U.S. Patent No. 5,501,133 to Brookstein et al. This patent was issued on March 26, 1996 and is entitled 30 "Apparatus for Making a Braid Structure".

At least the inner surface of the base fabric has 35 a coating of a polymeric resin material, such as polyurethane. The coating impregnates the base fabric and renders it impermeable to liquids, such as oil and

water, and is ground and buffed to provide it with smooth surface, and the belt with a uniform thickness.

The present invention will now be described in more complete detail with frequent reference being 5 made to the figures, which are listed and identified as follows.

Brief Description of the Drawings

Figure 1 is a side cross-sectional view of a long nip press;

10 Figure 2 is a perspective view of a belt of the present invention;

Figure 3 is a perspective view of an alternate embodiment of the belt; and

15 Figure 4 is a perspective view of another embodiment of the belt.

Detailed Description of the Preferred Embodiments

A long nip press for dewatering a fibrous web being processed into a paper product on a paper machine is shown in a side cross-sectional view in 20 Figure 1. The press nip 10 is defined by a smooth cylindrical press roll 12 and an arcuate pressure shoe 14. The arcuate pressure shoe 14 has about the same radius of curvature as the cylindrical press roll 12. The distance between the cylindrical press roll 12 and 25 the arcuate pressure shoe 14 may be adjusted by hydraulic means operatively attached to arcuate pressure shoe 14 to control the loading of the nip 10. Smooth cylindrical press roll 12 may be a controlled crown roll matched to the arcuate pressure shoe 14 to obtain a level cross-machine nip profile.

30 Long nip press belt 16 extends in a closed loop through nip 10, separating cylindrical press roll 12

from arcuate pressure shoe 14. A wet press fabric 18 and a fibrous web 20 being processed into a paper sheet pass together through nip 10 as indicated by the arrows in Figure 1. Fibrous web 20 is supported by 5 wet press fabric 18 and comes into direct contact with smooth cylindrical press roll 12 in nip 10. Fibrous web 20 and wet press fabric 18 proceed through the nip 10 as indicated by the arrows. Long nip press belt 16, also moving through press nip 10 as indicated by 10 the arrows, that is, counterclockwise as depicted in Figure 1, protects wet press fabric 18 from direct sliding contact against arcuate pressure shoe 14, and slides thereover on a lubricating film of oil. Long nip press belt 16, accordingly, must be impermeable to 15 oil, so that wet press fabric 18 and fibrous wet 20 will not be contaminated thereby.

A perspective view of the long nip press belt 16 is provided in Figure 2. The belt 16 has an inner surface 28 and an outer surface 30. On the outer 20 surface 30, the base fabric of the belt 16 may be visible.

Figure 3 is a perspective view of an alternate embodiment of the belt 32. The belt 32 has an inner surface 34 and an outer surface 36. The outer surface 25 36 is provided with a plurality of grooves 38, for example, in the longitudinal direction around the belt 32 for the temporary storage of water pressed from fibrous web 20 in press nip 10.

Alternatively, the outer surface of the belt may 30 be provided with a plurality of blind holes arranged in some desired geometric pattern for the temporary storage of water. Figure 4 is a perspective view of such an alternate embodiment of the belt 40. The belt 40 has an inner surface 42 and an outer surface 44. 35 The outer surface 44 is provided with a plurality of

blind holes 46, so called because they do not extend completely through the belt 40.

The long nip press belts 16, 32, 40 of the present invention include a base fabric which is a braided structure. The braided structure comprises a plurality of braided layers of yarns in which the layers are laid down in a single pass of a braiding machine, with at least one yarn of each layer extending into a contiguous layer to form an interlock between the layers.

The braided structure of the base fabrics may be manufactured according to the teachings of commonly assigned U.S. Patent No. 5,501,133 (the '133 patent) to Brookstein et al., entitled "Apparatus for Making a Braid Structure", the teachings of which are incorporated herein by reference. The '133 patent shows a multilayer braided structure in which the layers are interbraided. The interbraiding of the layers provides an interlock therebetween which prevents the delamination of multiple braided layers from one another.

The interlock between the layers may be a direct interlock in which the interlocking yarn passes from a first layer to a contiguous second layer, and passes around at least one yarn in the second layer.

Alternatively, the interlock between the layers may be an indirect interlock in which an interlocking yarn passes from the first layer through the second layer to another, not necessarily contiguous, layer in the structure, and passes around a strand in the other layer to serve to bind the first layer and the other layer together and at the same time to bind the layers therebetween.

To manufacture a base fabric for a long nip press belt, the braided structure may be of a hollow,

tubular form. In view of the fact that long nip press belts, depending on the size requirements of the long nip presses on which they are installed, have lengths from roughly 10 to 40 feet (approximately 3 to 12 meters), measured longitudinally around their endless-loop forms, and widths from roughly 100 to 450 inches (approximately 250 to 1125 centimeters), measured transversely across those forms, the production of the base fabric may require a cylindrical braiding mandrel 5 having a diameter from roughly 3 to 12 feet (approximately 1 to 4 meters) and a length from roughly 100 to 450 inches (approximately 250 to 1125 centimeters).

The multilayer braided structure of the base fabric is made by feeding a plurality of yarns from a first set of movable package carriers to a braid-forming area to form a braid layer thereat in which each movable package carrier traverses a predetermined first serpentine path, and by feeding a plurality of 10 yarns from a second set of movable package carriers to the braid-forming area to form a braid layer thereat in which each movable package carrier of the second set traverses a predetermined second serpentine path, wherein each of the serpentine paths is arranged so 15 that at least one package carrier of each set can carry a yarn from its respective layer into the other layer to interlock with the other layer.

As noted above, the second layer may be contiguous to the first layer. Alternatively, the 20 second layer may be spaced from the first layer and have a number of intermediate layers interposed therebetween. In such circumstances, a yarn associated with the package carrier moving between the first and second layers is used to pass through all

the intermediate layers prior to forming a positive interlock with the second layer.

Yarns from static package carriers may also be fed to the braid-forming area between two or more 5 layers for interbraiding with the yarns from the respective movable package carriers. The yarns fed from static package carriers maintain a longitudinal or axial orientation with respect to the cylindrical braiding mandrel. In this way, the base fabric may be 10 provided with reinforcement yarns lying in the transverse, or cross-machine, direction of the belt. Such reinforcement is useful where the belt is of the "press jacket" variety held by clamping rings on the widthwise edges of the press.

15 The cylindrical braiding mandrel may be positioned in the braid-forming area in order to form the requisite hollow braid structure. The first layer of the braid is then formed on the mandrel and second, and subsequent, layers are formed over the first 20 layer. The mandrel may be moved through the braid-forming area as braiding takes place so that a continuous hollow braided structure is built up thereon. All of the layers of the multilayer braided structure are laid down in one pass of the mandrel 25 through the braiding machine.

The plurality of package carriers and serpentine paths are arranged on the internal surface of a tubular braiding machine, the internal surface having a plurality of serpentine paths formed therein. 30 Movable package carriers traverse the serpentine paths; static package carriers are fixed on the internal surface of the tubular braiding machine.

The braid-forming area is preferably situated at the longitudinal axis of the tubular braiding machine 35 and, as the braided structure is formed, it, or, more

specifically, the cylindrical braiding mandrel is moved through the tubular braiding machine along the longitudinal axis thereof.

For use as the base fabric for a long nip press belt, the braided structure preferably consists of 5 yarns which make an angle of 85° or more to the longitudinal axis of the cylindrical braiding mandrel. In other words, the yarns of the base fabric will define left-handed and right-handed intertwined 10 spirals each making an angle of 5° or less with respect to the machine direction of the long nip press belt. This will make it less likely that the long nip press belt will distort in response to tension applied 15 in the machine direction, and can be accomplished by minimizing the number of movable package carriers used to make the braided structure.

The base fabric may be produced from any of the 20 yarn varieties used by those of ordinary skill in the art to produce papermachine clothing. Monofilament yarns are preferred, although plied monofilament, 25 multifilament and plied multifilament yarns may also be used. The yarns may be of any of the polymeric resins from which yarns for papermachine clothing are commonly extruded, such as polyamide, polyester, polyetheretherketone (PEEK), polyaramid and polyolefin resins.

The braided structure of the base fabric must be 30 of an openness sufficient to ensure its complete impregnation by the polymeric resin material with which it is to be coated. Complete impregnation eliminates the possibility of undesirable voids forming in the finished belt. Voids are particularly undesirable because they may allow the lubricating oil used between the belt and the arcuate pressure shoe to 35 pass through the belt and contaminate the press fabric

18, or press fabrics, and fibrous wet 20 being processed into paper.

When the braiding of the base fabric has been completed, it may be removed from the cylindrical 5 braiding mandrel and coated with a polymeric resin material using techniques well-known in the art. Alternatively, the coating may be carried out, at least in part, while the base fabric is still on the cylindrical braiding mandrel.

10 The polymeric resin material is applied to at least one surface of the base fabric, that surface being the one which will ultimately be the inner surface of the belt. As the inner surface slides across the lubricated arcuate pressure shoe 14, the 15 coating of polymeric resin material protects the base fabric from such sliding contact and the wear by abrasion that would otherwise result. The polymeric resin material also impregnates the base fabric and renders the belt impermeable to oil and water. The 20 polymeric resin material may be polyurethane, and, if so, is preferably a 100% solids composition thereof to avoid the formation of bubbles during the curing process through which the polymeric resin proceeds following its application onto the base fabric. After 25 curing, the coating of polymeric resin material is ground and buffed to provide the belt with a smooth surface and a uniform thickness.

Alternatively, both surfaces of the base fabric 30 may be coated with a polymeric resin material. Following the curing of the polymeric resin material, both the inner surface and the outer surface of the belt may be ground and buffed to provide the belt with smooth surfaces and a uniform thickness. Finally, the outer surface may be provided, by cutting, scoring, 35 graving or drilling, with a plurality of grooves, for

example, in the longitudinal direction around the belt, or blind holes for the temporary storage of water press from fibrous web 20 in the press nip 10.

It will be recognized that modifications to the  
5 above would be obvious to anyone of ordinary skill in  
the art without departing from the scope of the claims  
appended hereinbelow.

What Is Claimed Is:

1. A resin-impregnated endless belt for a long nip press or calender of the shoe type, or for other papermaking and paper-processing applications, said long nip press or calender having a cylindrical press roll and an arcuate pressure shoe which together define a nip therebetween, said resin-impregnated endless belt passing through said nip in direct, sliding contact with said arcuate pressure shoe and separating a fibrous web being treated in said nip,  
5 and perhaps a press fabric or fabrics supporting said fibrous web, from said arcuate pressure shoe, thereby protecting said fibrous web, and press fabric or fabrics, from damage by direct, sliding contact with said arcuate pressure shoe and from contamination by  
10 any lubricant on said arcuate pressure shoe, said resin-impregnated endless belt comprising:  
15 a base fabric, said base fabric being a braided structure having a plurality of braided layers of yarns, wherein in each of said layers at least one  
yarn thereof extends into a contiguous layer to form  
20 an interlock therebetween, said base fabric being in  
the form of an endless loop with an inner surface, an  
outer surface, a longitudinal direction and a  
transverse direction; and  
25 a coating of a polymeric resin material on at  
least said inner surface of said base fabric, said  
coating impregnating and rendering said base fabric  
impermeable to liquids, said coating being smooth and  
providing said belt with a uniform thickness.
2. A belt as claimed in claim 1 wherein said coating  
of a polymeric resin material is on both said inner  
surface and said outer surface of said base fabric.

3. A belt as claimed in claim 1 wherein said polymeric resin material is polyurethane.

4. A belt as claimed in claim 1 wherein said yarns are of a polymeric resin material selected from the group consisting of polyamide, polyester, polyetheretherketone (PEEK), polyaramid and polyolefin  
5 resins.

5. A belt as claimed in claim 1 wherein said yarns are of any of the varieties selected from the group consisting of monofilament, plied monofilament, multifilament and plied multifilament yarns.

6. A belt as claimed in claim 1 wherein said yarns make an angle of 5° or less with the longitudinal direction of said base fabric.

7. A belt as claimed in claim 1 further comprising a plurality of reinforcing yarns, said reinforcing yarns extending in said transverse direction of said base fabric between at least one pair of said layers  
5 of yarns.

8. A belt as claimed in claim 1 wherein said reinforcing yarns are of a polymeric resin material selected from the group consisting of polyamide, polyester, polyetheretherketone (PEEK), polyaramid and  
5 polyolefin resins.

9. A belt as claimed in claim 1 wherein said reinforcing yarns are of any of the varieties selected from the group consisting of monofilament, plied monofilament, multifilament and plied multifilament  
5 yarns.

10. A belt as claimed in claim 1 wherein said coating on said inner surface of said base fabric is ground and buffed to give said belt a uniform thickness and desired surface characteristics.

11. A belt as claimed in claim 2 wherein said coating on both said inner and outer surfaces is ground and buffed to give said belt a uniform thickness and desired surface characteristics.

12. A belt as claimed in claim 2 wherein said coating on said outer surface of said belt includes a plurality of grooves.

13. A belt as claimed in claim 2 wherein said coating on said outer surface of said belt includes a plurality of blind holes.
